

Problem Statement – Green Commute Planner

Urban transportation systems today heavily rely on private vehicles, leading to increased carbon emissions, traffic congestion, and environmental degradation. Many commuters lack awareness and accessible tools to evaluate the environmental impact of their daily travel choices. Existing navigation systems primarily focus on shortest distance or fastest routes, without considering sustainability factors such as carbon emissions or eco-friendly alternatives.

As a result, users are unable to make informed decisions regarding greener commuting options such as public transport, cycling, walking, or carpooling. This gap contributes to higher fuel consumption and environmental damage.

Therefore, there is a need for a system that enables users to compare multiple transportation options based on environmental impact and encourages the adoption of sustainable commuting practices.

The proposed Green Commute Planner aims to address this problem by suggesting eco-friendly routes, calculating carbon emissions, and recommending the most sustainable travel options using modern technologies such as mapping APIs and data-driven analysis.
